

# **MS test software: Applications to Canadian data**

**Peter Sullivan,  
Canadian Dairy Network**

# Introduction

---

- **Use of the software**
  - Flexibility and ease of use
  - Pre-processing requirements
  - Information / results generated
  - Post-processing opportunities
- **Impacts of ignoring genotypes in EBV calculation (i.e. GPS bias) on validation results**

# Use of the software

## Flexibility and ease of use

---

- **Easy to use**
- **Flexible** to different breeds, traits, population size, with suitable guidance in the documentation
- **Documentation is efficient**, being very helpful but not longer than necessary
- **Runs efficiently**... ~ 1 hour for all breeds and traits

# Use of the software pre-processing requirements

---

- **Need to create input files for each breed**
- **Can have 1 file with all traits OR by groups of traits OR separate files for each trait**
- **Input data file(s) include for each animal: pedigree, ebv (E) and reliabilities (R):**
  - an sire dam  $E_a E_s E_d R_a R_s R_d$
- **Input parameter file** specifies the name of data file to use, which traits within the file should be tested, and the range of years to include in the test

# Use of the software

## Information / results generated

---

- **Output information is divided among multiple files**  
\*.out, \*.dat, \*.summary, <console>
- **Provides yearly estimates of: genetic variance, average MS, PEV(MS)**
- **Tests for years with outlier variance**
  - Outlier if H0 rejected for a given year
- **Tests for non-zero trend in variance**
  - H0 rejected if BOTH statistical AND practical tests are FAILS
- **Warnings and good guidance if insufficient data**

# Use of the software

## Post-processing opportunities

---

- Approximate **PEV(MS)** provided in the output, which is otherwise difficult to obtain without this software
- The **subset of provided bulls actually used** for the test (e.g. PEV is low enough) are identified
- User can **modify input data** to test impacts on validation test results
  - Improve understanding of current EBV
  - Develop better EBV systems
- **Genomic Selection**
  - Test years prior to GPS (e.g. Bulls born 1998-2008)
  - Modify EBVs to see impact of GPS 

# Genomic Selection for positive Mend. Sampling

- Selection intensity for genomic young bulls has increased dramatically... **1 in 20 (5%)** chosen for **use in AI**
- Positive within-family deviations for important traits at the time of GPS selection (i.e. before AI use) ...  **$MS_{GPS} > 0$**  for **70-100%** of GPS bulls (CAN,NLD,DFS data)
- After AI, the MS deviations from EBV (ignoring genotypes) of these same bulls are regressed strongly towards 0 ...  **$MS_{EBV} > 0 \rightarrow 50%$**
- $MS_{GPS}$  is very high, while  $MS_{EBV}$  is much closer to zero
- Recent trends in EBV are much lower due to this downward bias of MS for GPS bulls ( **$b_{EBV} \sim 50\% * b_{GEBV}$** )

# Future EBV will not be biased by Genomic PreSelection (GPS)

---

- Genetic evaluation centres will develop methodology to reduce/eliminate GPS bias in EBV of dairy cattle
- Corrections to remove GPS bias will likely increase  $\%MS>0 \sim 100\%$  and will increase  $b_{EBV} \sim b_{GEBV}$
- How will this affect results from Interbull Validation test 4, which tests the following hypothesis?  
**H0: For each year,  $MS \sim N(0, V_0)$**
- Since GPS creates truncated distribution of MS, so H0 is dramatically unrealistic... Accepting H0 means:
  1. GPS effects are small, or power of the test is weak.
  2. EBV are biased / do not reflect the true effects of GPS

# What might future EBV look like if NOT biased by GPS?

- Consider changes that would increase  $b_{EBV} \sim 2 * b_{EBV}$  and increase %MS>0 from **50%  $\sim 100%$** , while not changing the EBV of very best GPS bulls (e.g. 3 st. Deviation above the average of birth year cohorts)

$$Top_0 = a + b_{EBV} * yr + 3\sigma_e$$

$$b_{EBV}^* = 1.25, 1.50, 1.75, 2.00$$

$$Top_1 = a + b_{EBV}^* * yr + 3\sigma_1$$

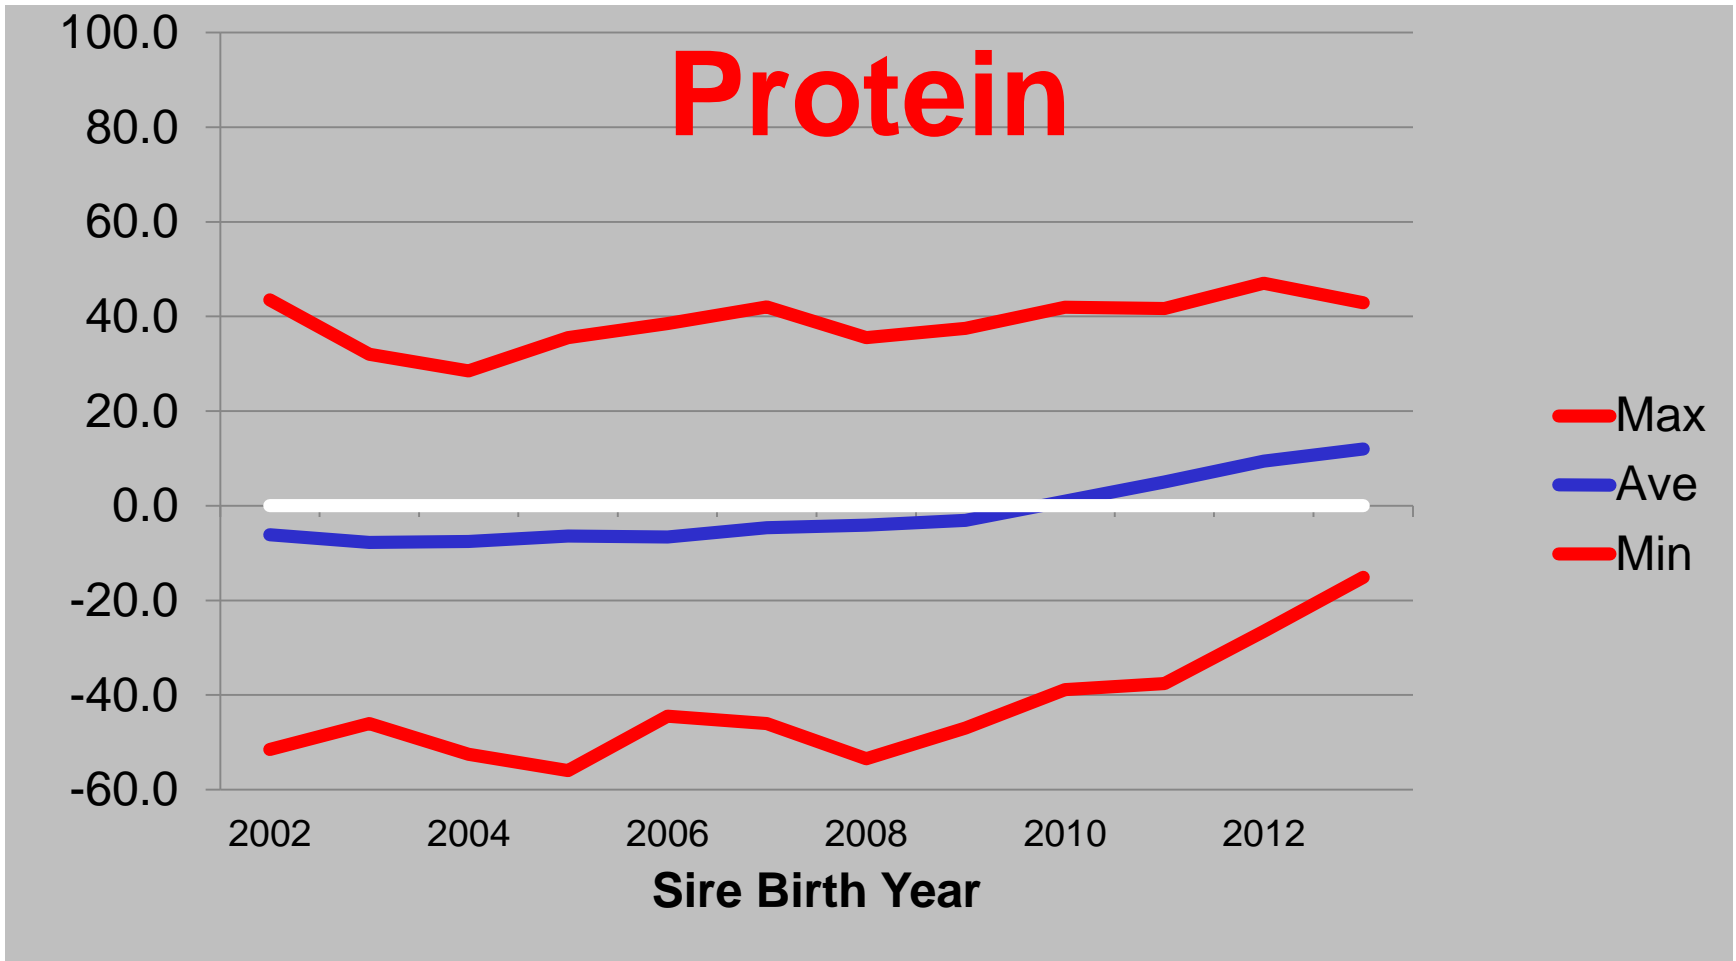

Solve for  $\sigma_1$ , such that  $Top_1 = Top_0$

Scale EBV-E(EBV) by  $\sigma_1 / \sigma_e$

# Range of $MS_{EBV}$ with EBV ignoring genotypes (GPS bias)

# Range of $MS_{EBV}$ with EBV adjusted for GPS: $b_{EBV} * 1.50$

# Range of $MS_{EBV}$ with EBV adjusted for GPS: $b_{EBV} * 2.00$

# GPS bulls are the best full-sibs: move %MS>0 from 50% ~> 100%

# GPS affects on ITB validation Test4 (Trends in average MS)

# GPS affects on ITB validation Test4 (Trends in variance)

# MS Variance Test Protein

---

- If EBV without genotypes include GPS bias, then the **biased EBV will PASS** the variance trend test (ITB test 4)
- If EBV are corrected to account for GPS, then the **unbiased EBV will FAIL** the variance trend test (ITB test 4)
  - Intensity of GPS is **HIGH** for Protein

# GPS affects on ITB validation Test4 (Trends in average MS)

# GPS affects on ITB validation Test4 (Trends in variance)

# MS Variance Test Conformation

---

- If EBV without genomics include GPS bias, then the **biased EBV will PASS** the variance trend test (ITB test 4)
- If EBV are corrected to account for GPS, then the **unbiased EBV will FAIL** the variance trend test (ITB test 4)
  - Intensity of GPS is **HIGH** for **Conformation**

# GPS affects on ITB validation Test4 (Trends in average MS)

# GPS affects on ITB validation Test4 (Trends in variance)

# MS Variance Test

## Udder Support

---

- If EBV without genomics include GPS bias, then the **biased EBV will PASS** the variance trend test (ITB test 4)
- If EBV are corrected to account for GPS, then the **unbiased EBV will PASS** the variance trend test (ITB test 4)
  - Intensity of GPS is **LOW** for **Udder Support**

# Summary

---

- **Software is flexible, efficient, easy to use**
- **Results of the validation test are NOT RELEVANT to decide inclusion/exclusion of national EBV as input to MACE**
  - GPS-Biased EBV pass the test
  - Unbiased EBV fail the test
- **Software is a very useful tool for “GE systems mining”**
  - Good quality information/data is generated, to allow detailed tracing and post-analysis of within and between family estimates of genetic differences... To improve understanding of GE systems behaviours and for developing improved systems
