

Using a Parameter Space to Improve GMACE Results

P.G. Sullivan

Canadian Dairy Network

GMACE (1512)

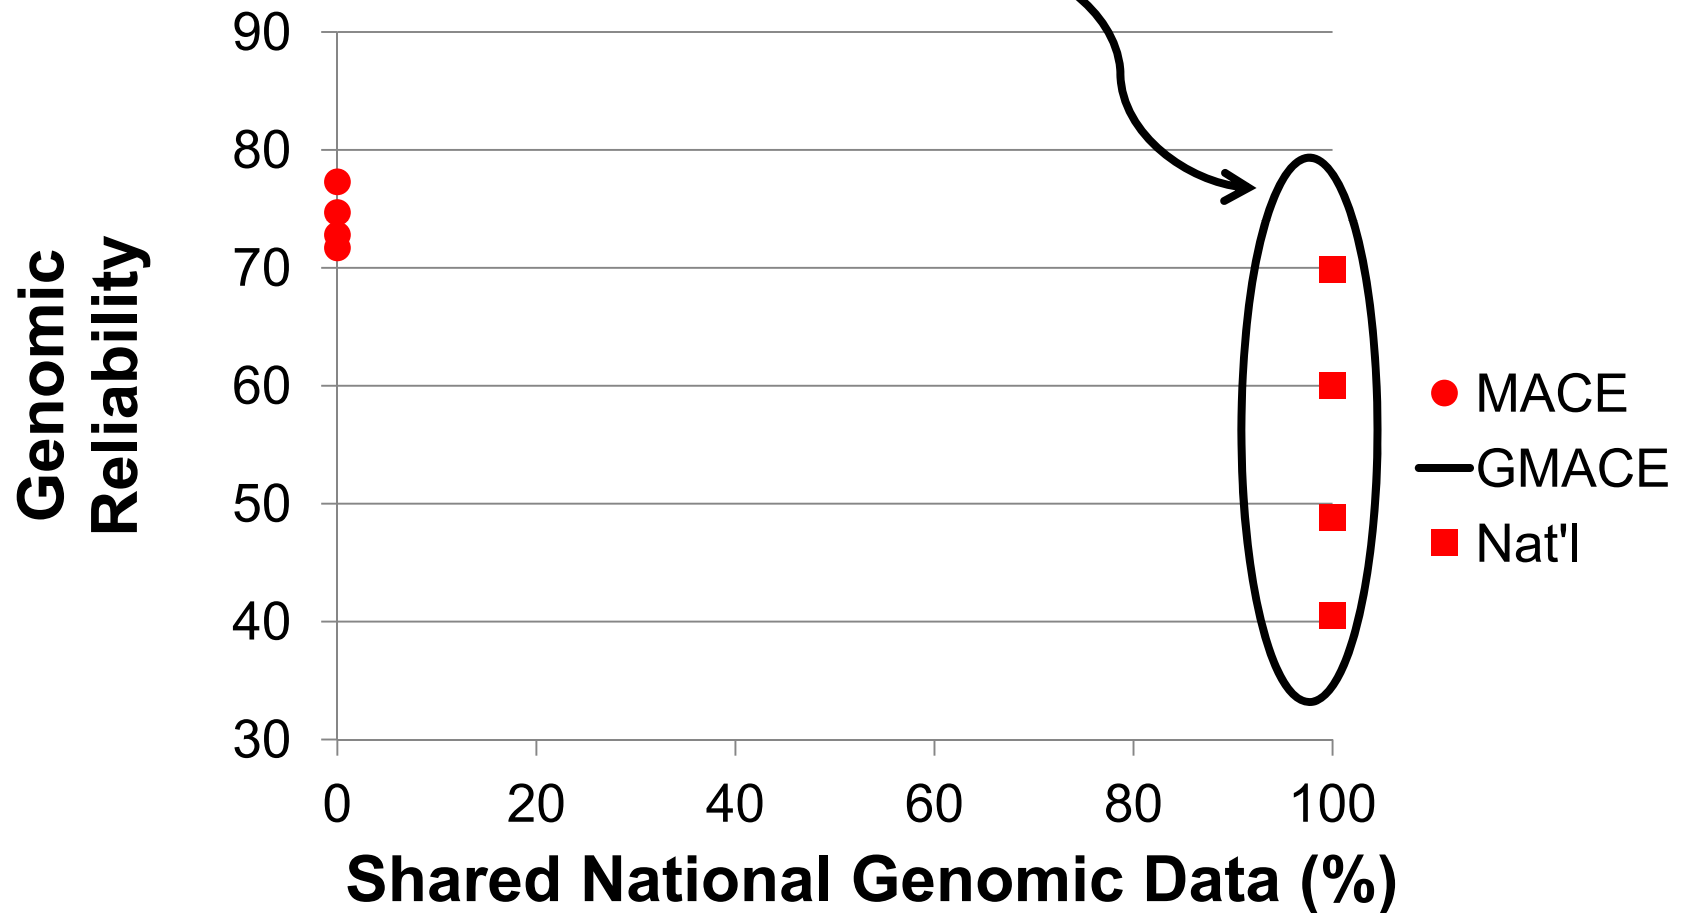

(MAS:NLD) What's wrong?

Introduction

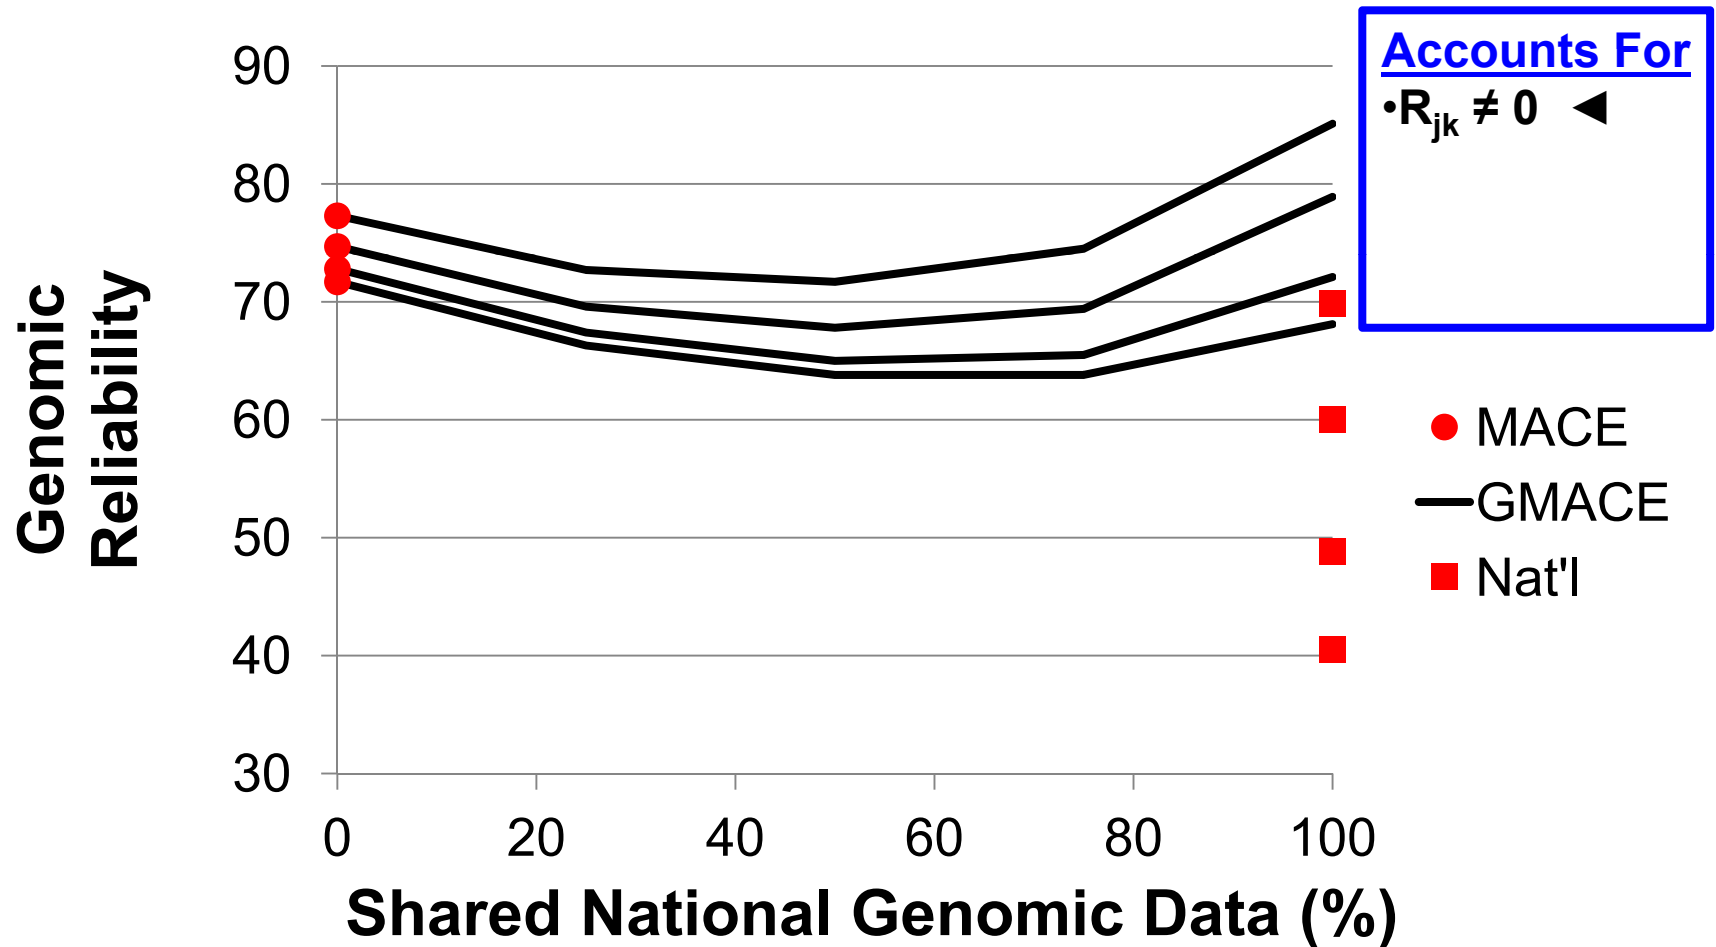

- **National Reliabilities lower** for MAS than SCS
- **GMACE Reliabilities higher** for MAS than SCS
 - **Question:** Where does the **extra information** come from in the GMACE evaluation for MAS?
 - **1 Answer:** **much lower residual correlations** (r_e) were used in GMACE for MAS (**WHY?**) ... quick review of r_e :
 - **MACE:** independent daughter phenotypes by country → $r_e = 0$
 - **GMACE:** genomic sharing → $r_e > 0$ (VanRaden & Sullivan, 2010)
 - Revised definition → **lower r_e** (Sullivan & VanRaden, 2011)
 - Predicted Reliability → **higher r_e** (Sullivan and Jakobsen, 2014)
 - Routine GMACE service begins (Aug 2014)

Example: 4 countries national reliabilities differ

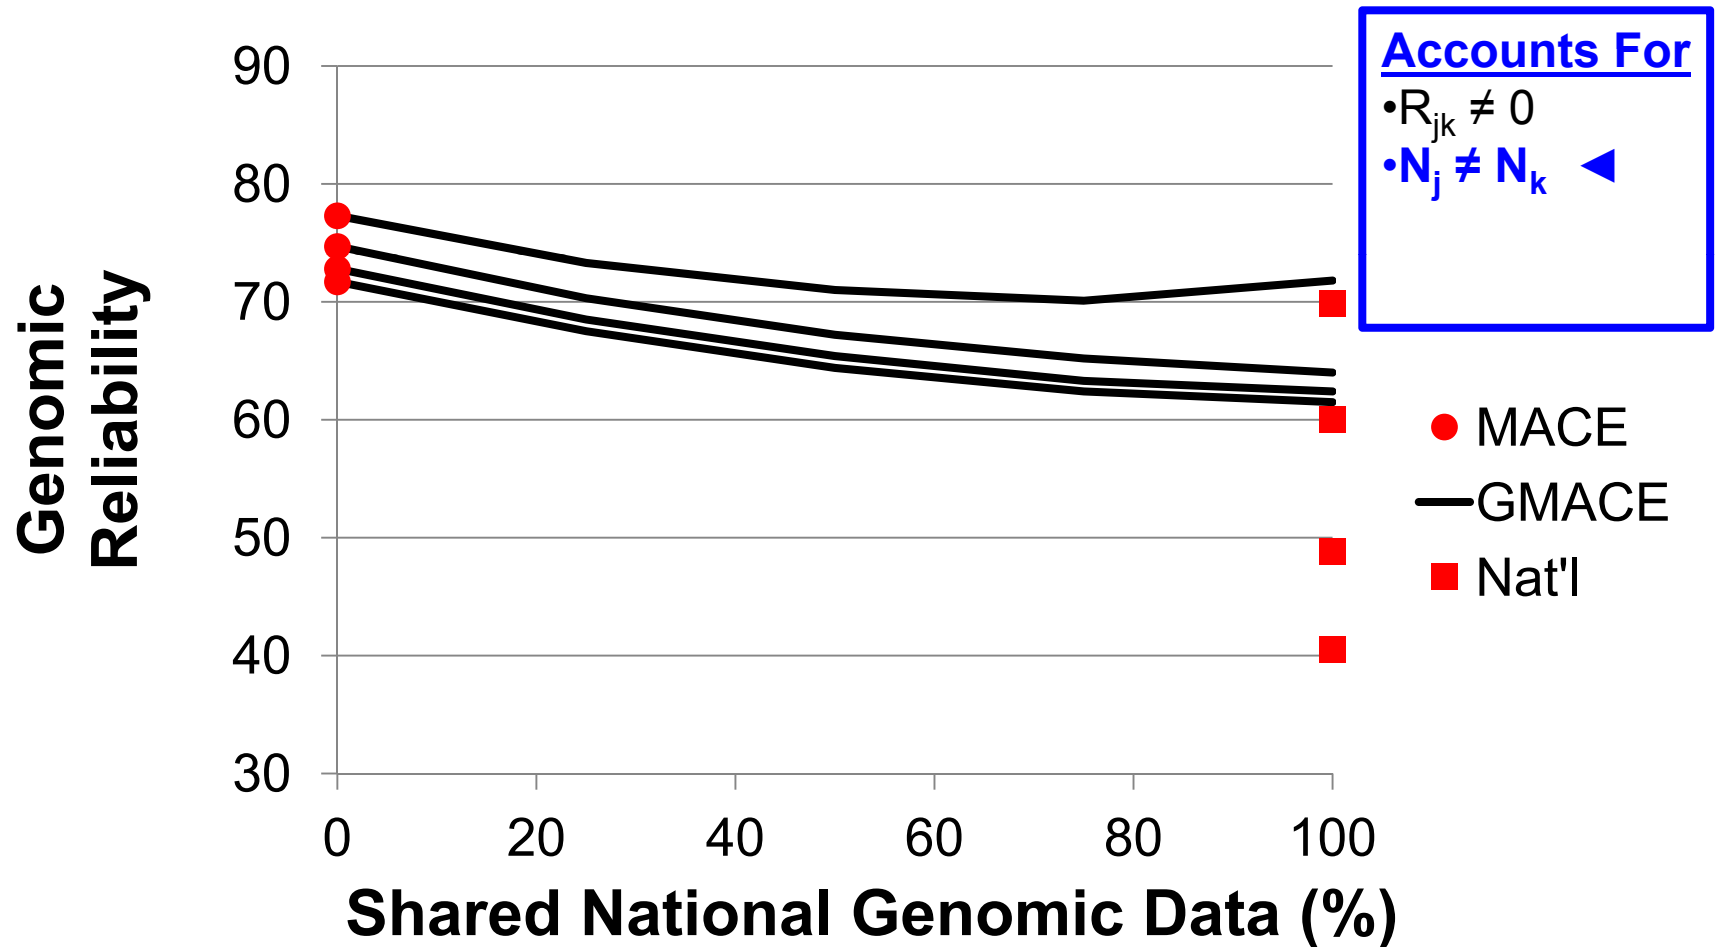

Example: 4 countries

GMACE: 2010

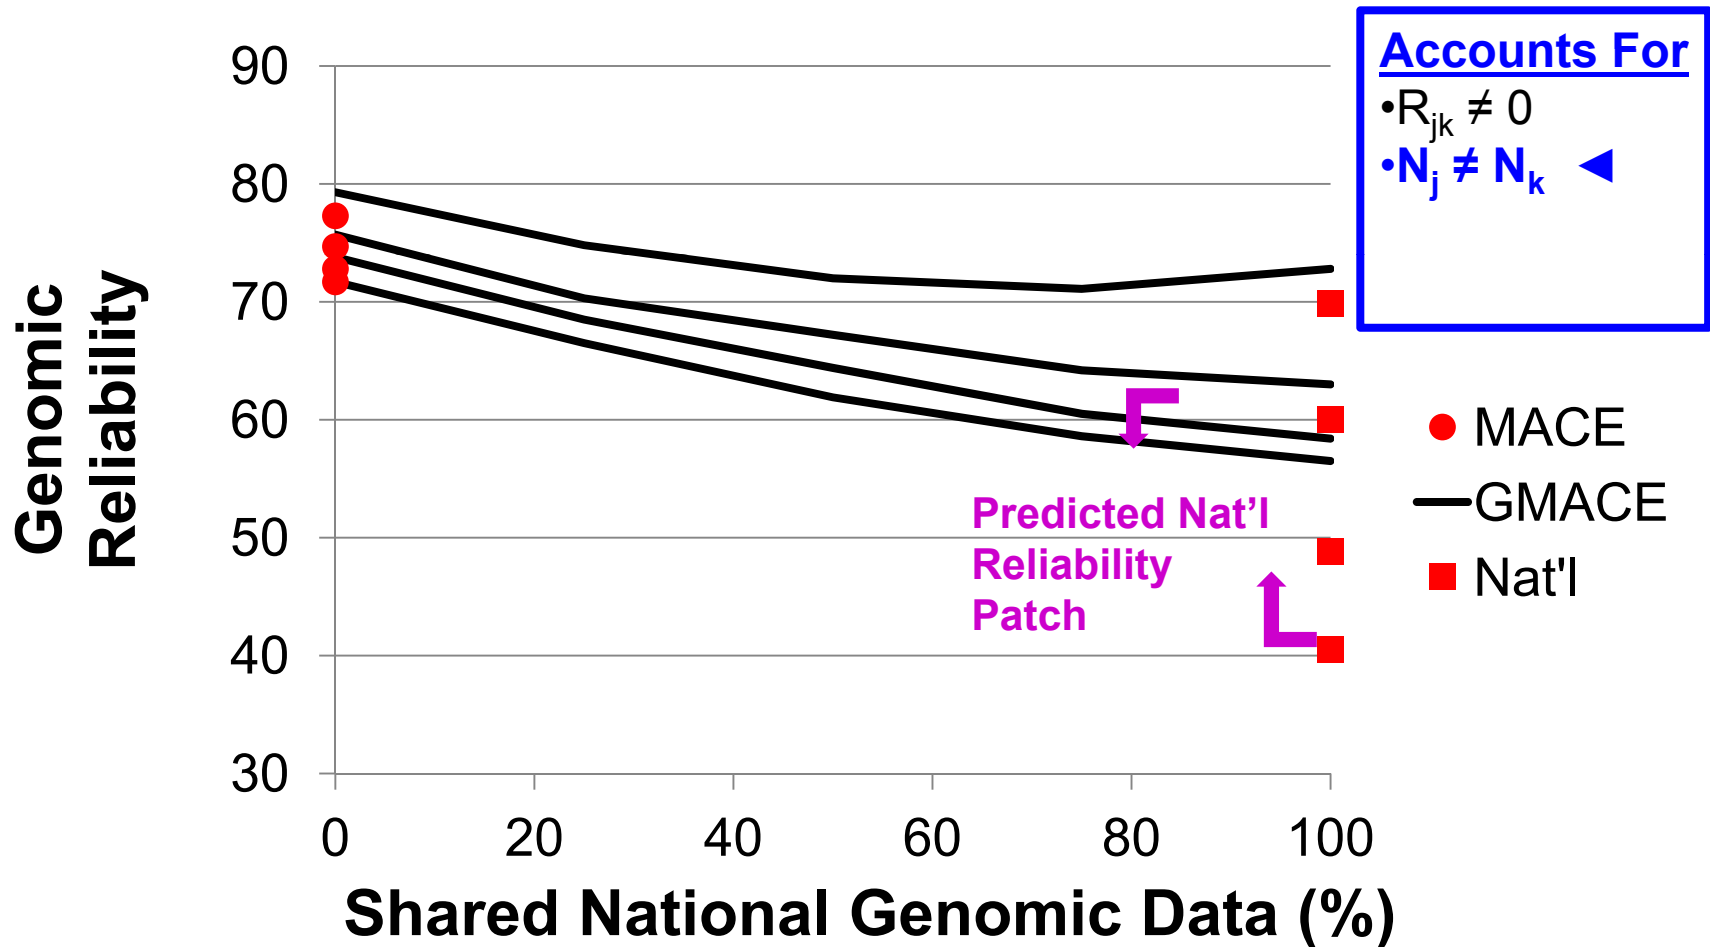

Example: 4 countries

GMACE: 2011

Example: 4 countries Interbull GMACE: 2014

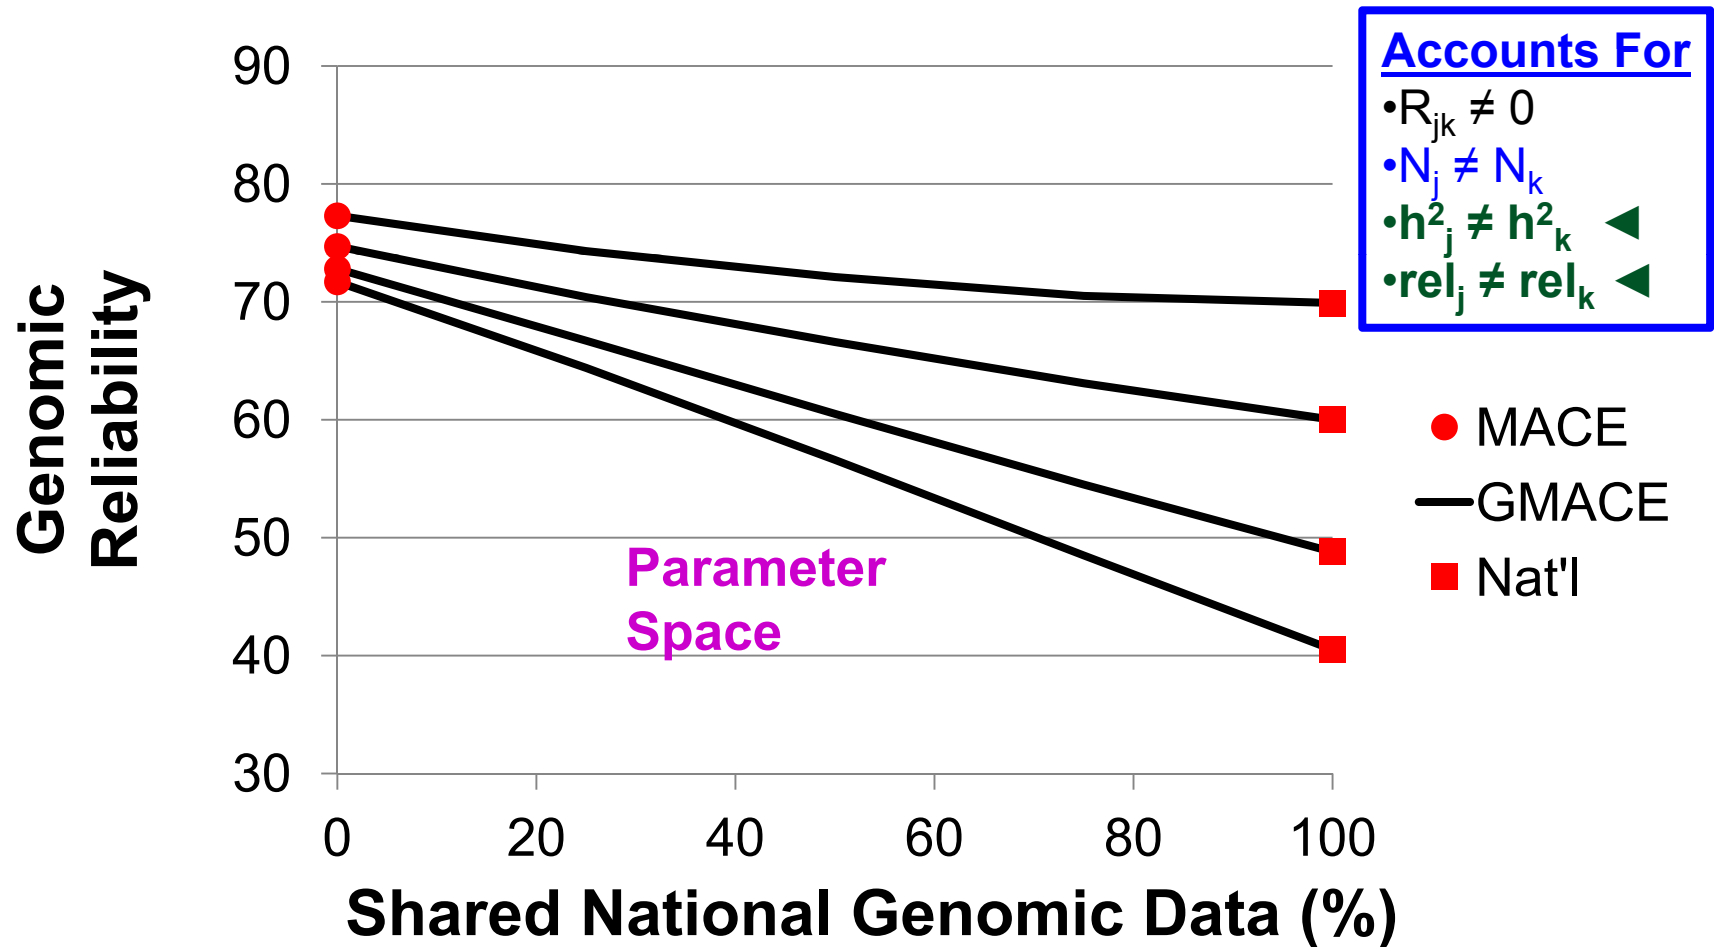

Example: 4 countries

GMACE: 2017

Example: 4 countries

New GMACE: 2017

GMACE (1512)

(MAS:NLD) What's wrong?

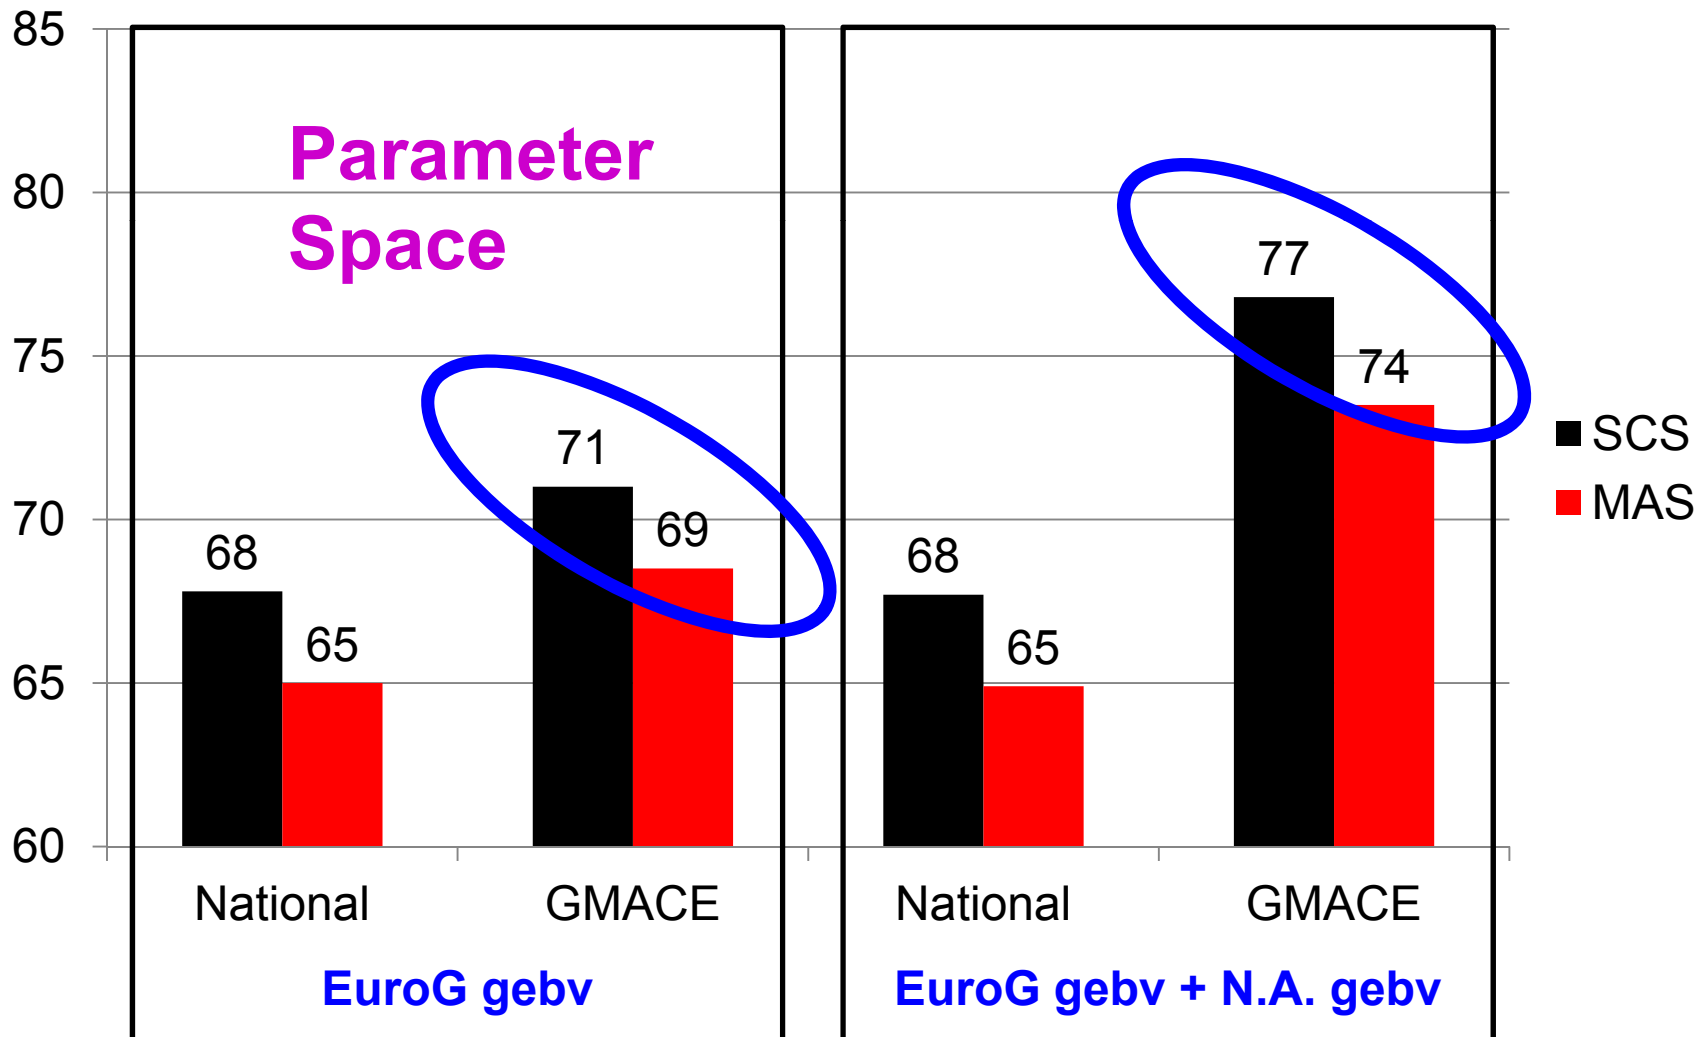

GMACE (1609)

(MAS:NLD) What's wrong?

New GMACE (1609) (MAS:NLD) Much Better

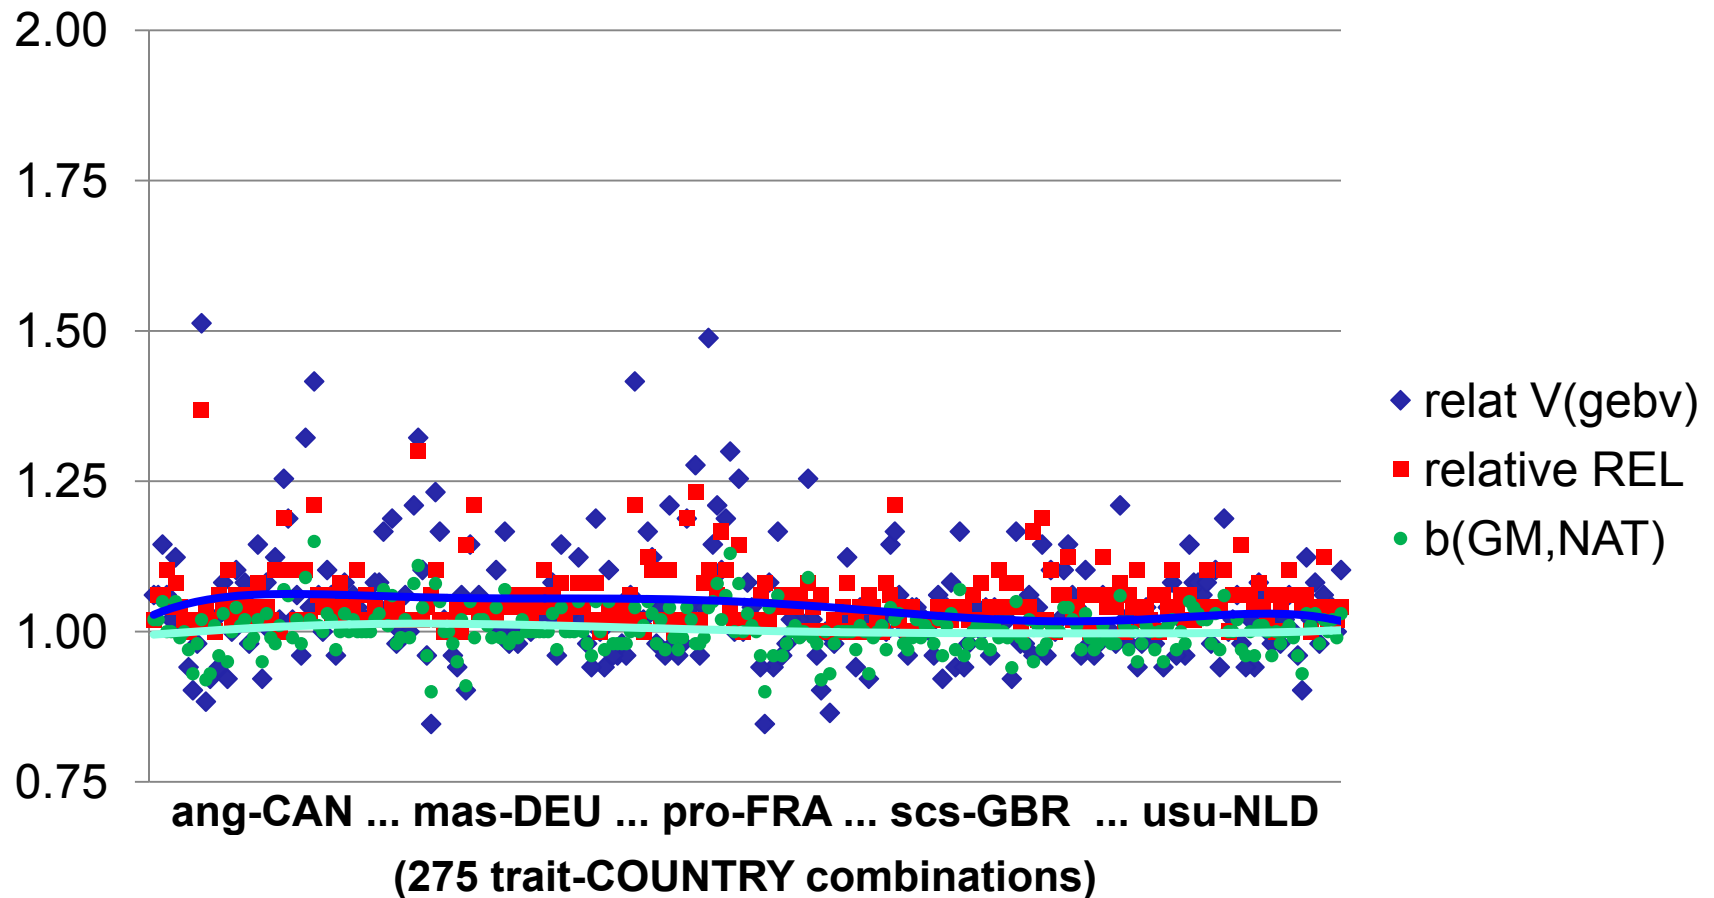

Interbull GMACE (1609) (GEBV from 1 Consortium)

Interbull GMACE (1609) (GEBV from 1 Consortium)

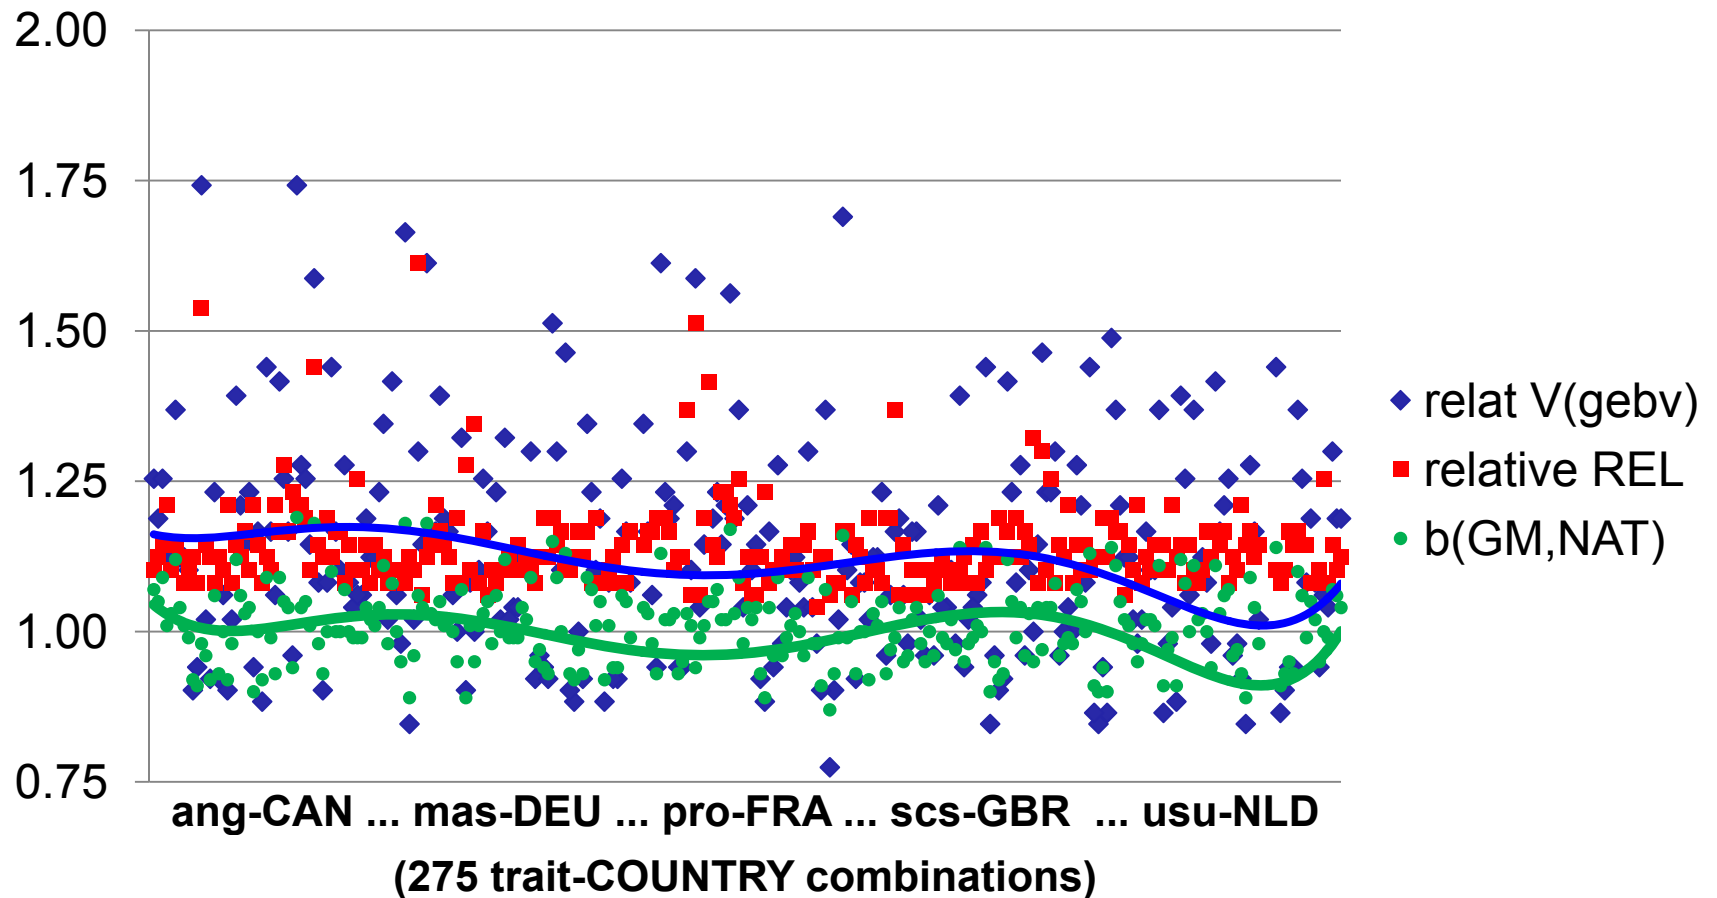

Interbull GMACE (1609) (GEBV from 1 Consortium)

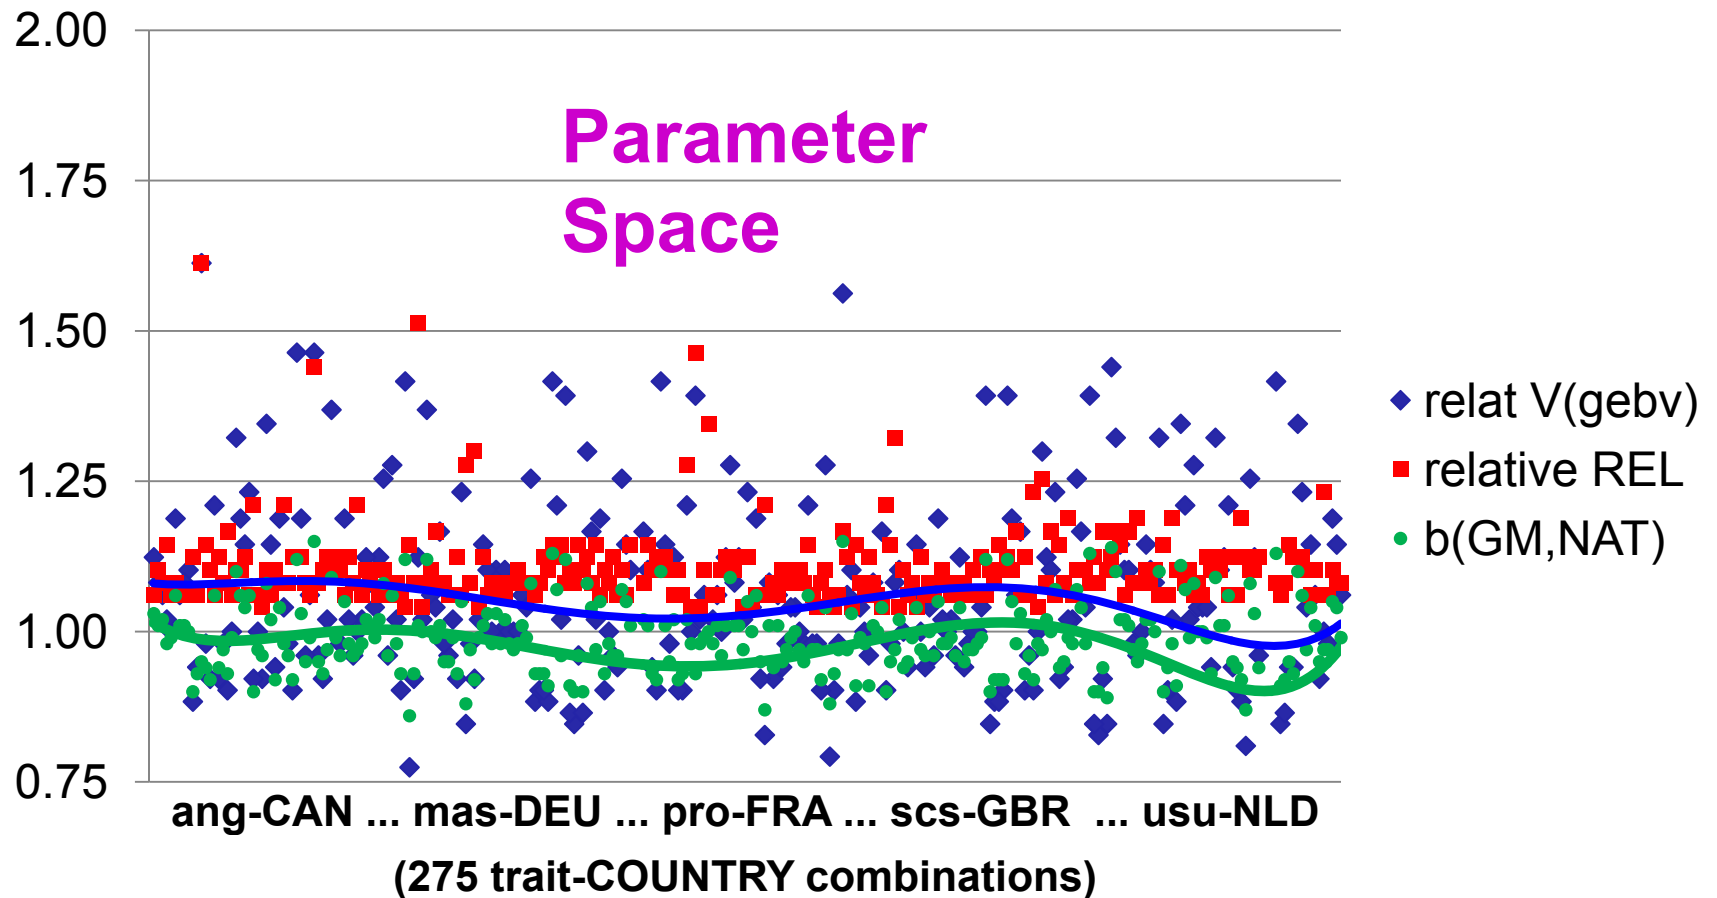

New GMACE (1609) (GEBV from 1 Consortium)

Interbull GMACE (1609) (GEBV from 2 Consortia)

New GMACE (1609) (GEBV from 2 Consortia)

Summary

- **Valid Concerns** about **GMACE** for **MAS**
 - reliabilities inflated → $V(\text{gebv})$ inflated
- **Solution:**
 1. Choose residual correlations that perfectly align **GMACE** of **highest reliability** country with:
 - National reliability if countries share all genotypes
 - MACE if no genomic data are shared ($r_e=0$)
 2. Need to impose a **parameter space** to **extend** this same alignment to all lower-reliability countries
- Approach works much better and **eliminates the need for predicted reliability patch**

Summary

- **GMACE results will become:**
 - Much **more consistent across all traits**,
 - Aligned perfectly between MACE and all National, based on level of **genomic data sharing**,
 - Alignment no longer disrupted by variation in trait **heritabilities** or **national reliabilities**
- **Increases from national Reliab'y & V(gebv):**
 - **Zero for bulls with GEBV from 1 country**
 - **Nearly zero if multiple GEBV from 1 consortium**
 - **Notably greater than zero, but less than before if GEBV from 2 consortia**

Recommendation

- **New methodology and results were reviewed by ITC during Aug/Sep 2016**
 - Recommendation to **implement the new GMACE model as soon as possible**
- **Next steps**
 - Update/test Interbull systems for routine and test runs
 - Use the new model for January 2017 GMACE test run
 - **Implementation for April 2017 GMACE routine run**
