# Business Mtg (Aug 2013)

## Impacts of national GRELn on GMACE

**“Simulate” GRELn errors:**

**Predict with a regression equation:**

**GRELn = trait + size of local reference + size of foreign reference + error**

**Two GMACE runs:**

- 1. Using as input: GRELn**
- 2. Using as input: GRELn – error**

**Relate change in GRELn input to changes in GMACE parameters and results**

# Objectives

- Predict national genomic reliabilities (N):  
$$N = f(\textit{trait, reference pop'n, methods})$$
- Apply GMACE using different sets of national reliability input data:
  - *National reliabilities* as provided by countries
  - *Predicted reliabilities* from  $f()$

# Data

- December 2013 implementation run
  - GEBV from 11 evaluation centres
    - A. [CAN, GBR, ITA, USA] ... Share genotypes
    - B. [DEU, DFS, FRA, NLD] ... Share genotypes
    - C. [AUS] [CHR] [POL]
  - 37 of the 38 MACE traits
    - Production: *Protein* (*pro*), ...
    - Conformation: *Stature* (*sta*), ...
    - Udder Health: *SCS*, *Clinical Mastitis* (*scs*, *mas*)
    - Longevity: (*dlo*), ...
    - Calving: *Direct Stillbirth* (*dsb*), ...
    - Fertility: *Cow Conception 1* (*ccl*), ...
    - Workability: (*msh*)

# Methods – Predicting Reliability

- Exponential transformation of Reliability (N) creates a linear relationship with genomic reference population size:

$$\exp(N) = \text{Trait} + b_1 L + b_2 F + M + e$$

- **L** =  $\sum \text{Rel}(\text{EBV})$  ... Local bulls
- **F** =  $\sum \text{Rel}(\text{MACE})$  ... Foreign bulls
- **M** = SNP panels used, imputations, %polygenic, SNPs evaluated, EBV-DGV blending, ...

# Methods – Predicting Reliability

- Exponential transformation of Reliability (N) creates a linear relationship with genomic reference population size:

$$\exp(N) = \text{Trait} + b_1L + b_2F + M + e$$
$$\exp(N) = (\text{Trait} + b_1L + b_2F) + E$$

- **M** = SNP panels used, imputations, %polygenic, SNPs evaluated, EBV-DGV blending, ...

# Methods – Predicting Reliability

- Exponential transformation of Reliability (N)

$$\exp(N) = \text{Trait} + b_1 L + b_2 F + M + e$$

$$\exp(N) = (\text{Trait} + b_1 L + b_2 F) + E$$

- **M** = SNP panels used, imputations, %polygenic, SNPs evaluated, EBV-DGV blending, ...

# Methods – Predicting Reliability

- Exponential transformation of Reliability (N)

$$\exp(N) = \text{Trait} + b_1 L + b_2 F + \boxed{M + e}$$

$$\exp(N) = (\text{Trait} + b_1 L + b_2 F) + E$$

$$P = \text{predicted } N = \log(\text{Trait} + b_1 L + b_2 F)$$

- P eliminates  $E = (M + e)$ ... but we want to keep M and eliminate only the e portion of E.
- M = SNP panels used, imputations, %polygenic, SNPs evaluated, EBV-DGV blending, ...

# Methods – Predicting Reliability

$$\exp(N) = (\text{Trait} + b_1L + b_2F) + E$$

$$P = \text{predicted } N = \log(\text{Trait} + b_1L + b_2F)$$

- P eliminates  $E = (M + e)$ ... but we want to keep  $M$  and eliminate only the  $e$  portion of  $E$ .
- Assuming national evaluation centres do a good job of approximating  $N$ , then we can include  $M$  by finding an (optimum?) intermediate value between  $P$  and  $N$ , for example:

$$P.25 = 0.25 * P + 0.75 * N$$

$$P.5 = 0.50 * P + 0.50 * N$$

$$P.75 = 0.75 * P + 0.25 * N$$

## Cow Conception I

- A N
- A P.5
- B N
- B P.5

# Reliability Difference (foreign GMACE – national)

## Direct Stillbirth

# Observations

- **Re-genotyping foreign bulls locally**
  - *National genomic reliability will be higher than GMACE reliability for bulls with GEBV in only 1 or 2 foreign countries (on average)*
  - *GMACE reliability will be higher than national if bulls have GEBV in many foreign countries*
- **After the bull is genotyped locally**
  - *GMACE reliability will increase and always be equal or higher than the national reliability*
- **Same pattern with P.5 versus N**
